THANKS!

Motivation

Imaging and spectral analysis of gamma-ray data

Diffuse & point sources

„Model-free“ (use image statistical properties only)

One-shot, self-consistent :

all sources and diffuse simultaneously

Sources can be as weak as desired (unresolved populations)

Formal, objective – no manual intervention.

Bayes Theorem

s = signal

d = data

$$\mathcal{P}(s|d) = \frac{\mathcal{P}(d|s) \mathcal{P}(s)}{\mathcal{P}(d)}$$

Prob (signal | data) ~ Prob(data | signal) X Prob(signal)

Bayes Theorem

s = signal

d = data

$$\mathcal{P}(s|d) = \frac{\mathcal{P}(d|s) \mathcal{P}(s)}{\mathcal{P}(d)} = \frac{1}{Z(d)} e^{-H(d,s)}$$

Prob (signal | data) ~ Prob(data | signal) X Prob(signal)

Inference problem as a statistical field theory

$s =$ signal

$d =$ data

$$\mathcal{P}(s|d) = \frac{\mathcal{P}(d|s) \mathcal{P}(s)}{\mathcal{P}(d)} = \frac{1}{Z(d)} e^{-H(d,s)}$$

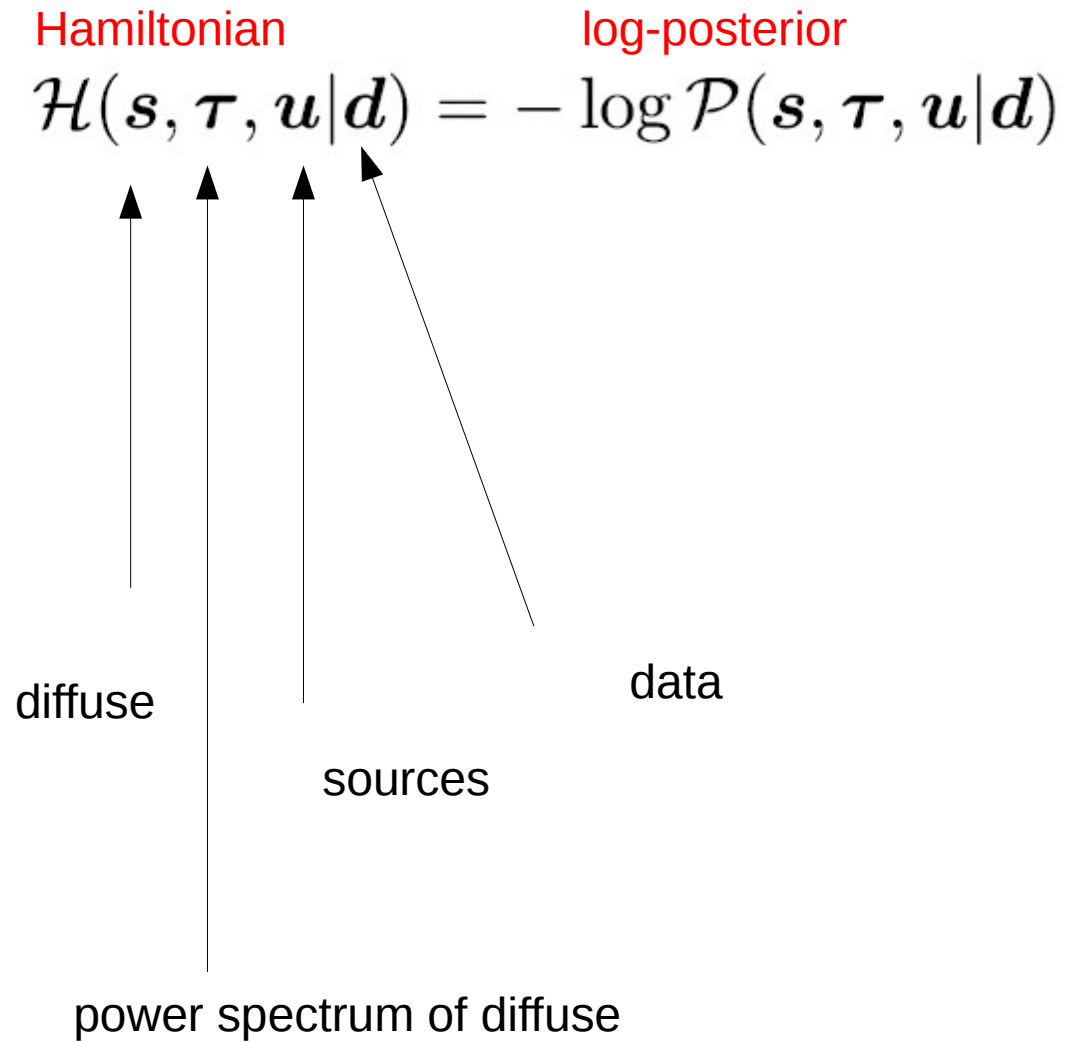

$$H(d, s) = -\log \mathcal{P}(d, s)$$

$$Z(d) = \int \mathcal{D}s \mathcal{P}(d, s)$$

Maximise $P \rightarrow$ maximize $-H \rightarrow$ minimize H

In words: *minimize information energy of field.*

It is a mathematical equivalence.

Hamiltonian

log-posterior

$$\begin{aligned}\mathcal{H}(\mathbf{s}, \boldsymbol{\tau}, \mathbf{u} | \mathbf{d}) &= -\log \mathcal{P}(\mathbf{s}, \boldsymbol{\tau}, \mathbf{u} | \mathbf{d}) \\ &= H_0 + \mathbf{1}^\dagger \mathbf{R} (e^{\mathbf{s}} + e^{\mathbf{u}}) - \mathbf{d}^\dagger \log (\mathbf{R} (e^{\mathbf{s}} + e^{\mathbf{u}}))\end{aligned}$$

Poisson log-likelihood

data

Hamiltonian

log-posterior

$$\begin{aligned}\mathcal{H}(\mathbf{s}, \boldsymbol{\tau}, \mathbf{u} | \mathbf{d}) &= -\log \mathcal{P}(\mathbf{s}, \boldsymbol{\tau}, \mathbf{u} | \mathbf{d}) \\ &= H_0 + \mathbf{1}^\dagger \mathbf{R} (e^{\mathbf{s}} + e^{\mathbf{u}}) - \mathbf{d}^\dagger \log (\mathbf{R} (e^{\mathbf{s}} + e^{\mathbf{u}})) \\ &\quad + \frac{1}{2} \log (\det [\mathbf{S}]) + \frac{1}{2} \mathbf{s}^\dagger \mathbf{S}^{-1} \mathbf{s} \\ &\quad + (\boldsymbol{\alpha} - \mathbf{1})^\dagger \boldsymbol{\tau} + \mathbf{q}^\dagger e^{-\boldsymbol{\tau}} + \frac{1}{2} \boldsymbol{\tau}^\dagger \mathbf{T} \boldsymbol{\tau} \\ &\quad + (\boldsymbol{\beta} - \mathbf{1})^\dagger \mathbf{u} + \boldsymbol{\eta}^\dagger e^{-\mathbf{u}}\end{aligned}$$

Poisson log-likelihood

Prior for diffuse

Prior for sources

5 parameters in prior:

3 for diffuse

2 for point sources

Diffuse: **Gaussian random field in log flux**, with 2-point correlation function specified through an **unknown power spectrum** controlled by 3 hyperparameters

Point sources: present **in each pixel, uncorrelated**, $dN/dS =$ power law with lower flux cutoff

IFT Dictionary

Translation:

field inference problem → statistical field theory

$$\mathcal{P}(s|d) = \frac{\mathcal{P}(d|s) \mathcal{P}(s)}{\mathcal{P}(d)} = \frac{1}{Z(d)} e^{-H(d,s)}$$

Dictionary:

log joint PDF	=	negative Hamiltonian
evidence	=	partition function Z
Wiener variance	=	information propagator
noise weighted data	→	information source
inference algorithms	←	Feynman diagrams
maximum a Posteriori	=	classical solution
uncertainty corrections	=	loop correction
Shannon information	=	negative entropy

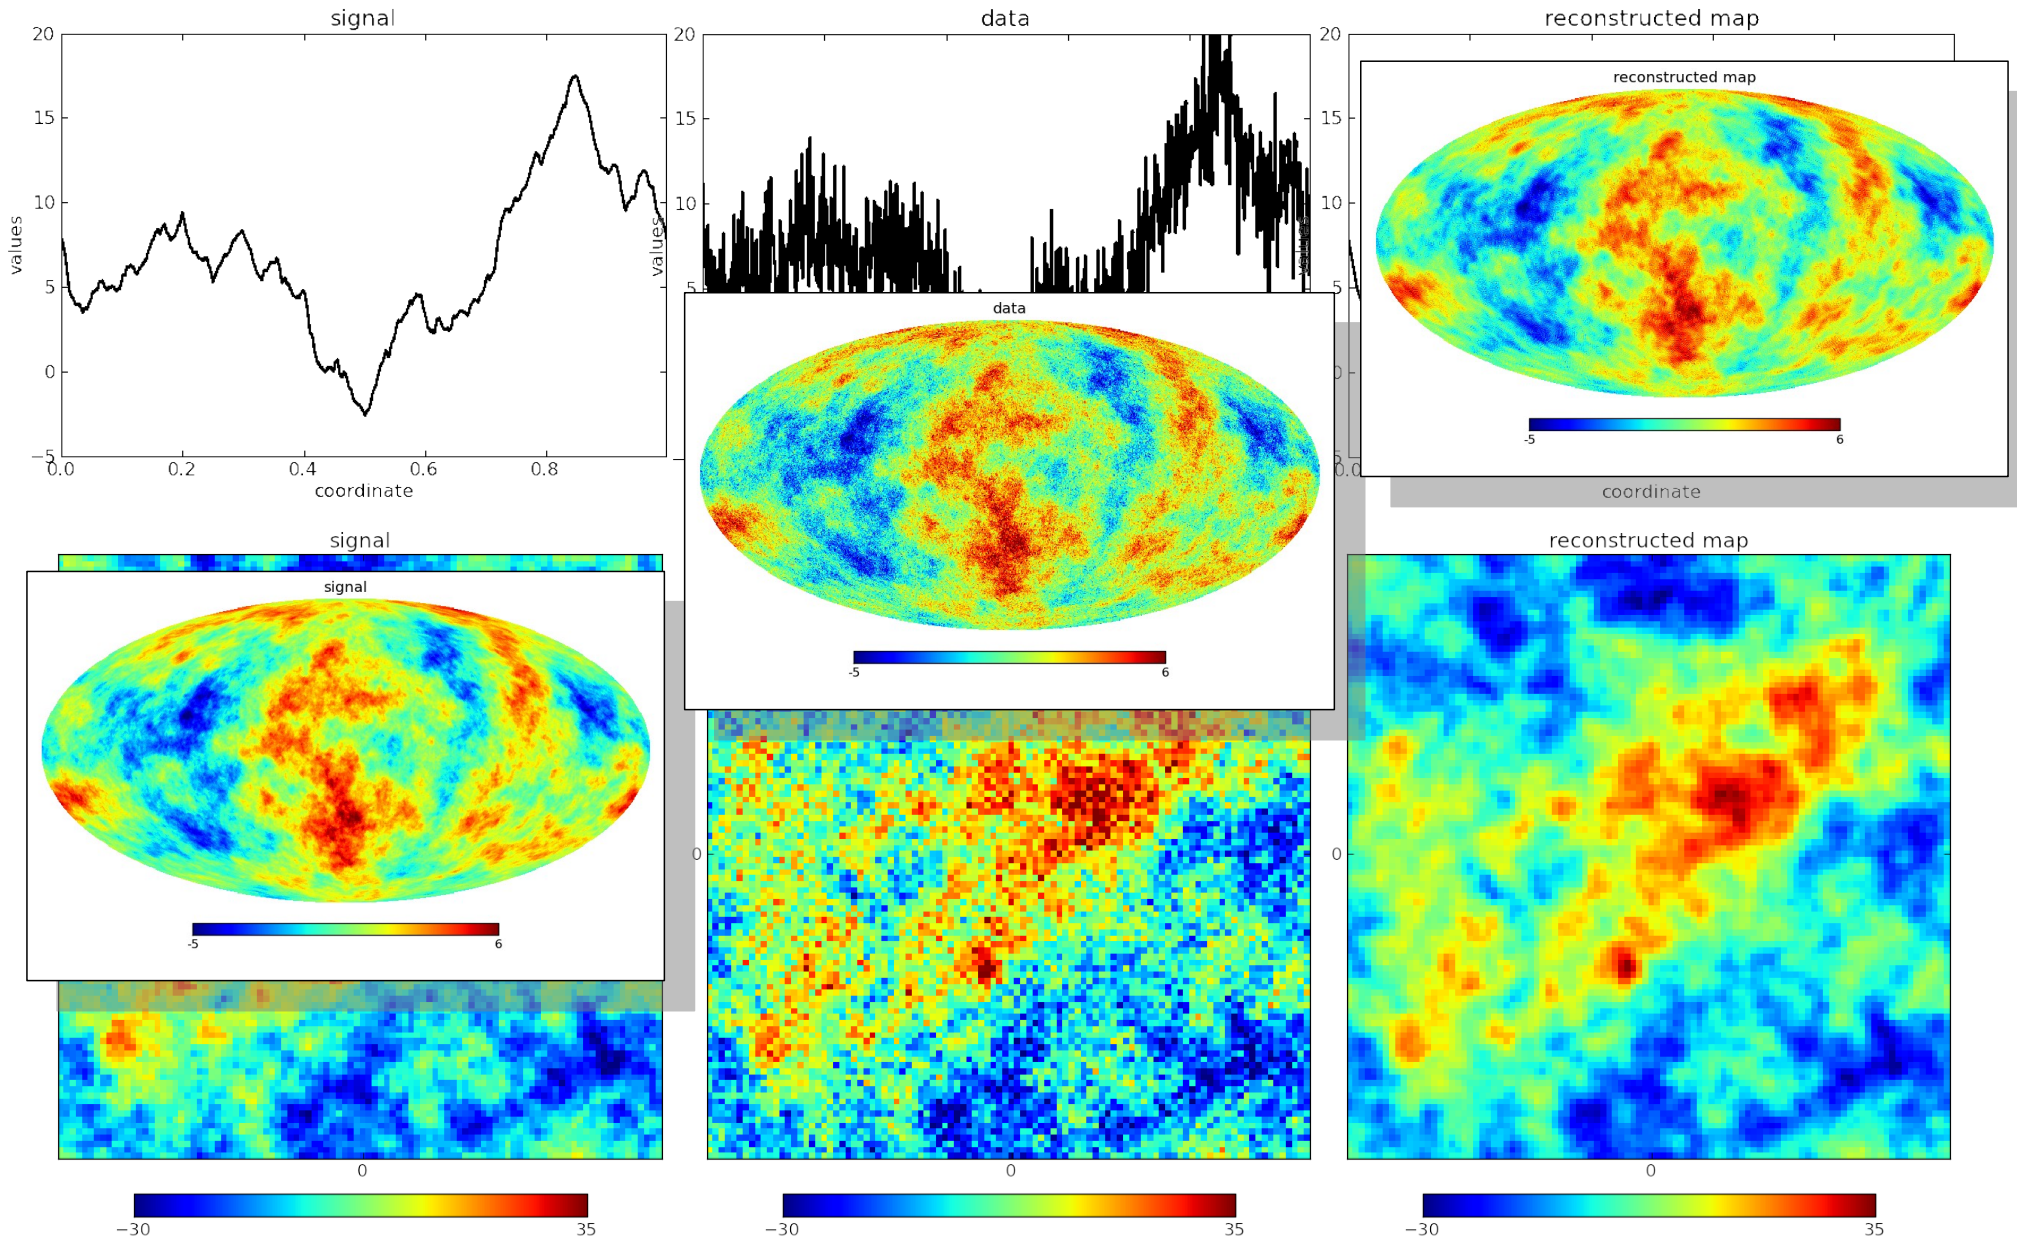

Use QFT methods to do the formal analysis
